# Outline

- Objectives
  - Review of Austin motivation
  - Review of PW motivation for prior efforts
- Background of Prior Effort
  - Approach
  - Validation
  - Benefits

# Ultrasonic POD

## Components of historic method:

- FBH amplitudes evaluated at various depths with a “wedding cake” sample.
- Variability for various transducers, systems, and operators evaluated but effects not separated for impact on POD.
- One sample per alloy produced which does not account for grain noise due to variability in microstructure from part to part.

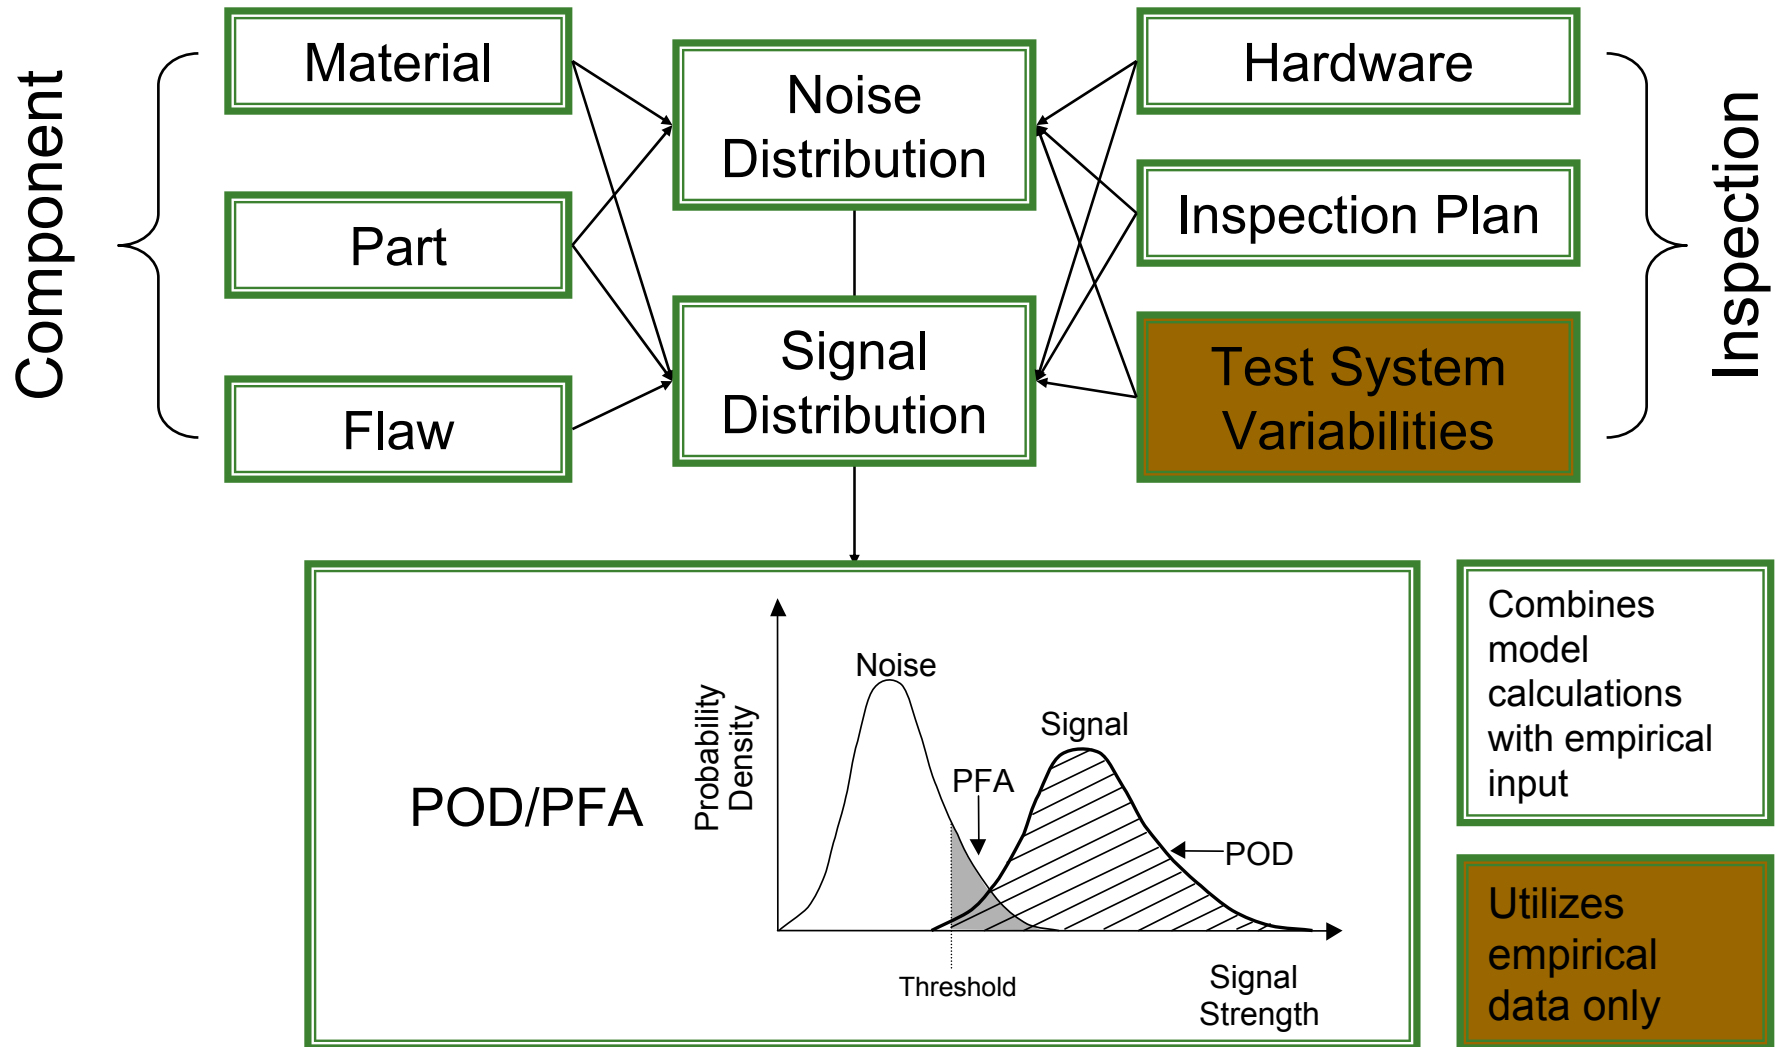

# Ultrasonic POD

## Components of model assisted method:

- FBH amplitudes predicted using a validated simulation model.
- Variability for various transducers, systems, and operators are assessed (through measurement) and the separate contributions to variability are evaluated.
- The effect of grain noise due to microstructure is evaluated empirically for a wide population of samples to account for variation in microstructure.
- POD is calculated for other parts and truly representative microstructures based on simulated signal amplitudes and measured grain noise.

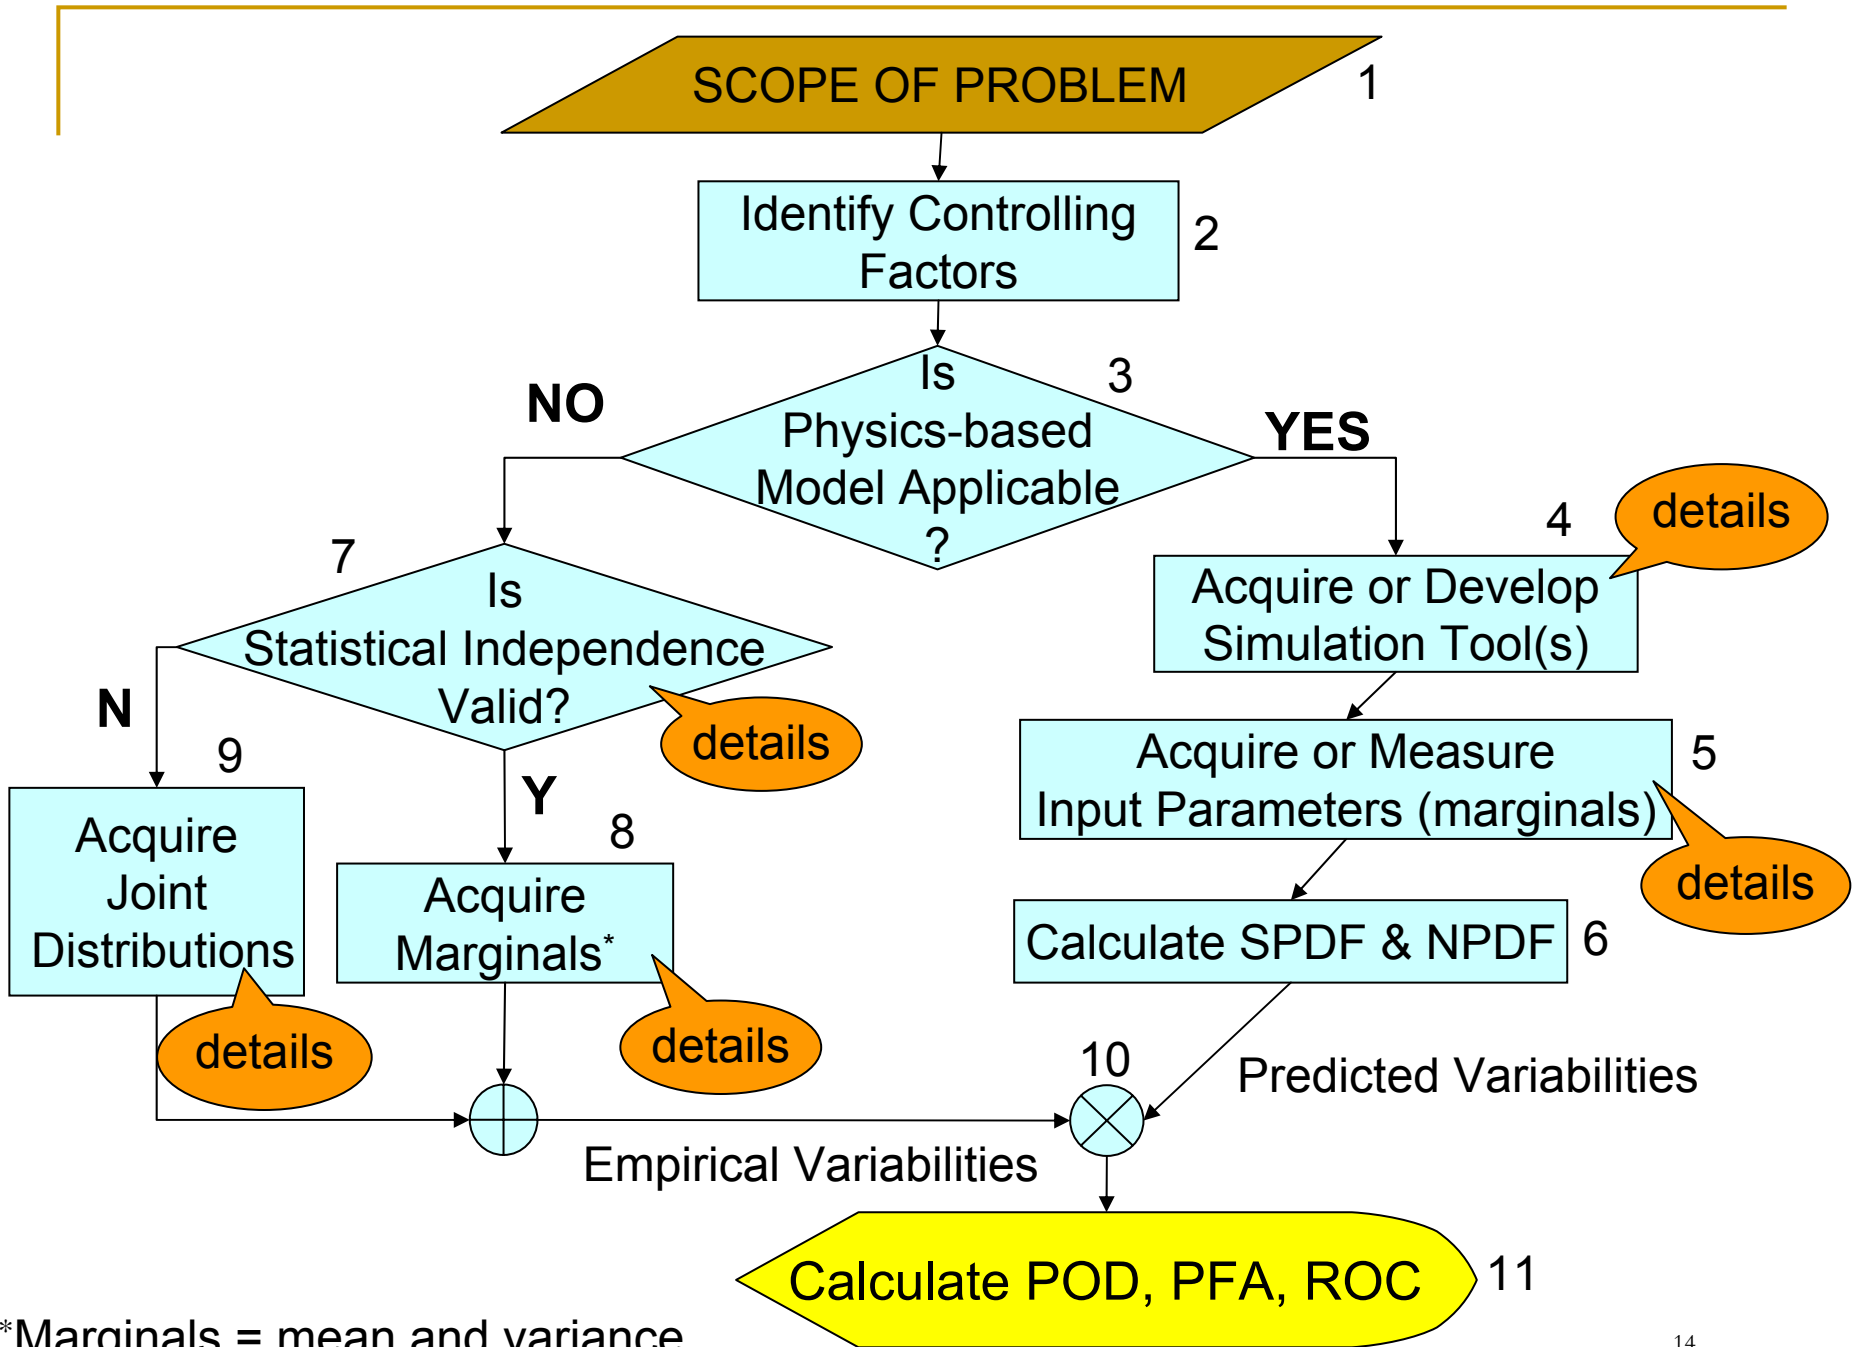

# POD Modular Methodology

# Steps to Generate Model-assisted UT POD

- Determine necessary UT properties
- Establish noise distribution for alloy/system using validated model
  - Material noise
  - Electronic noise
- Calculate signal distribution for inspection parameter set using validated model
  - Transducer
  - Threshold, scan plan
- Apply test system variability factor

\*Marginals = mean and variance

## Step 2. Controlling Factors

## Step 3. Identify Physics Model Applicable

Physics-Based Prediction

| Factor   | Single Valued Input Parameter (Nominal) | Distribution of Input Parameters | Empirical |
|--|---|----------------------------------|-----------|
| <b>Transducer/Hardware</b>                                 |   |                                  |           |
| f, $\Delta f$  | √                                       |                                  |           |
| Diam   | √                                       |                                  |           |
| Focal Length   | √                                       |                                  |           |
| Orientation  | √                                       |                                  |           |
| Standoff   |   |                                  |           |
| <b>Part/Material</b>                                       |   |                                  |           |
| Shape  | √                                       |                                  |           |
| Density  | √                                       |                                  |           |
| Wave Speed   | √                                       |                                  |           |
| Attenuation  |   | √ <sup>a</sup>                   |           |
| Backscattering Noise (FOM)                                 |   | √ <sup>a</sup>                   |           |
| <b>Flaw</b>  |   |                                  |           |
| FBH  | √                                       |                                  |           |
| <b>Electronic Noise</b>                                    |   |                                  | √         |
| <b>Test System Variability (Including Operator Set-up)</b> |   |                                  | √         |

a. Part-Part Variation Due to Microstructure Dependence

# From Spencer's Comments in Albuquerque MAPOD Minutes

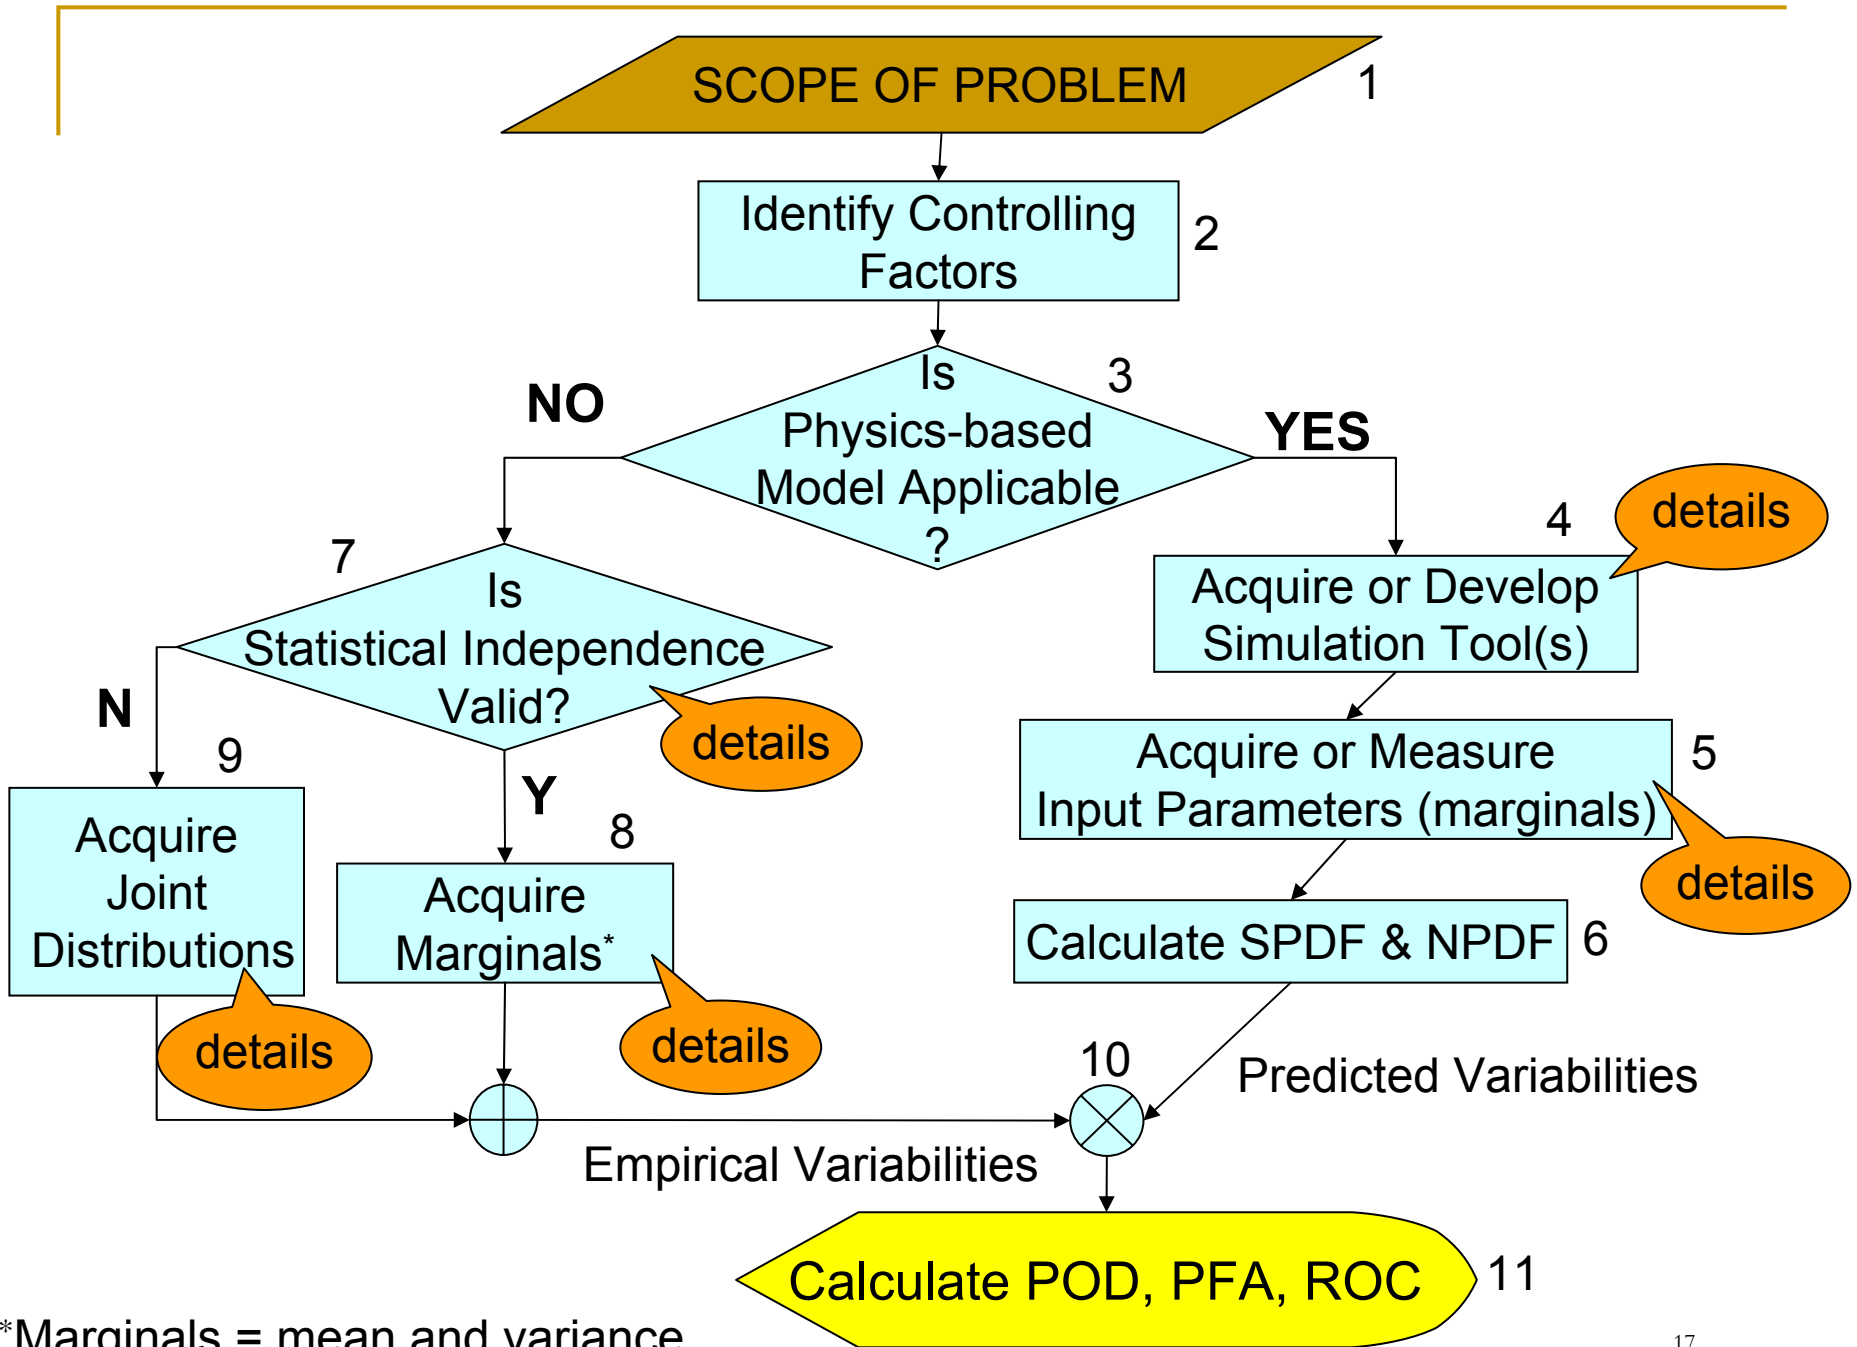

Influence of parameter variations on POD

Left: Distribution of input parameters

Right: Fixed input parameters

\*Marginals = mean and variance

## Step 4. Acquire or Develop Simulation Tools

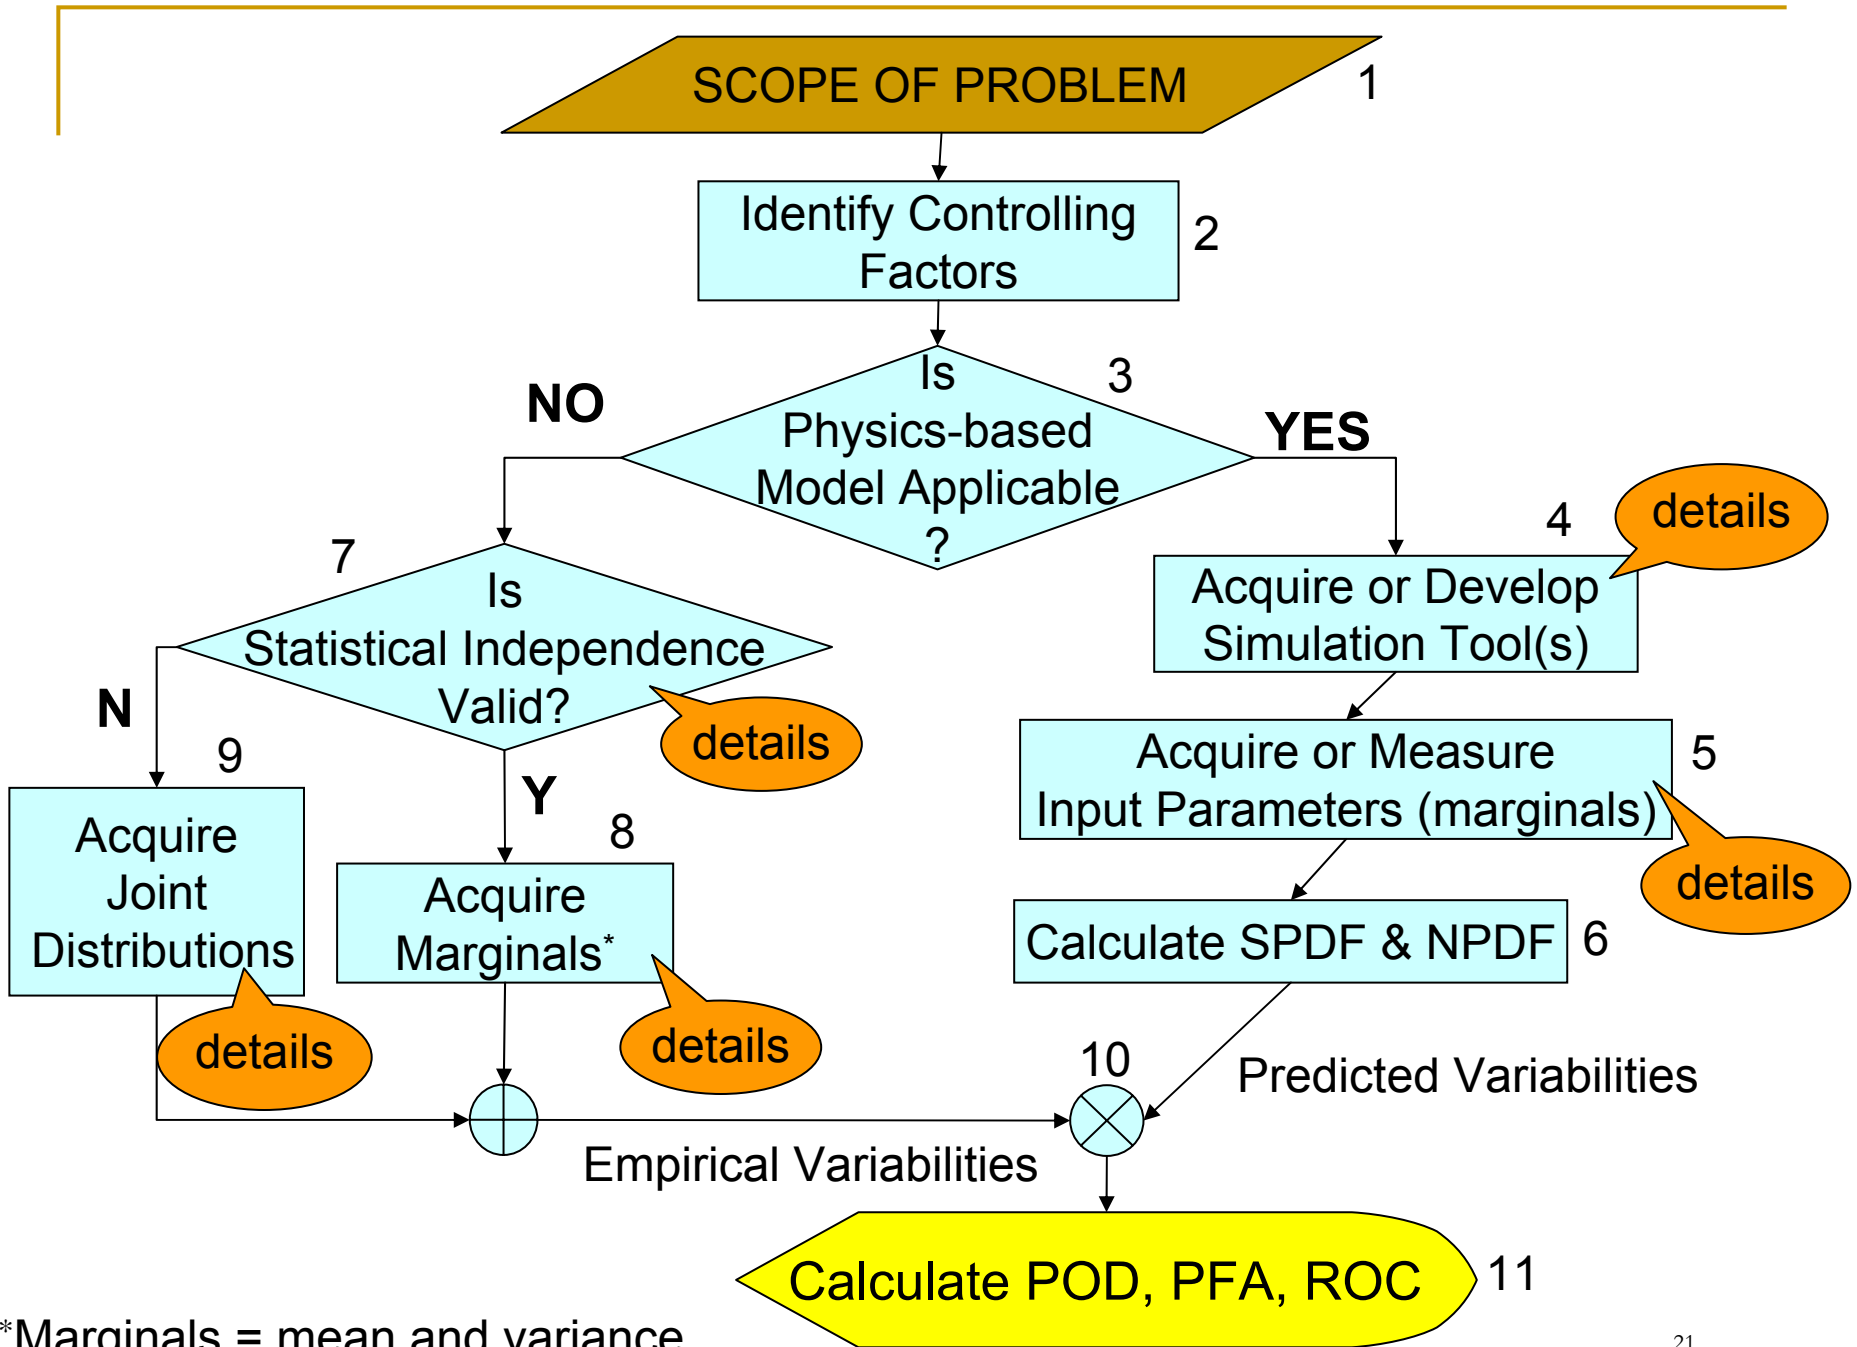

- Models for response of FBH developed on ETC Program
- Validations from ETC plus additional measurements as needed

# Step 5. Acquire or Measure Input Parameters

- Implied in viewgraph of Step 2
  - Variabilities of attenuation and FOM

## Step 6. Calculate SPDF & NPDF

- Physics Model → Effects of backscattered noise  
(FOM the empirical input parameter)
- Empirical measurements → Effects of electronic noise
- Distributions assumed normal with standard deviations controlled by above

## Step 7. Empirical Factors Statistically Independent?

- Physical analysis suggested independence

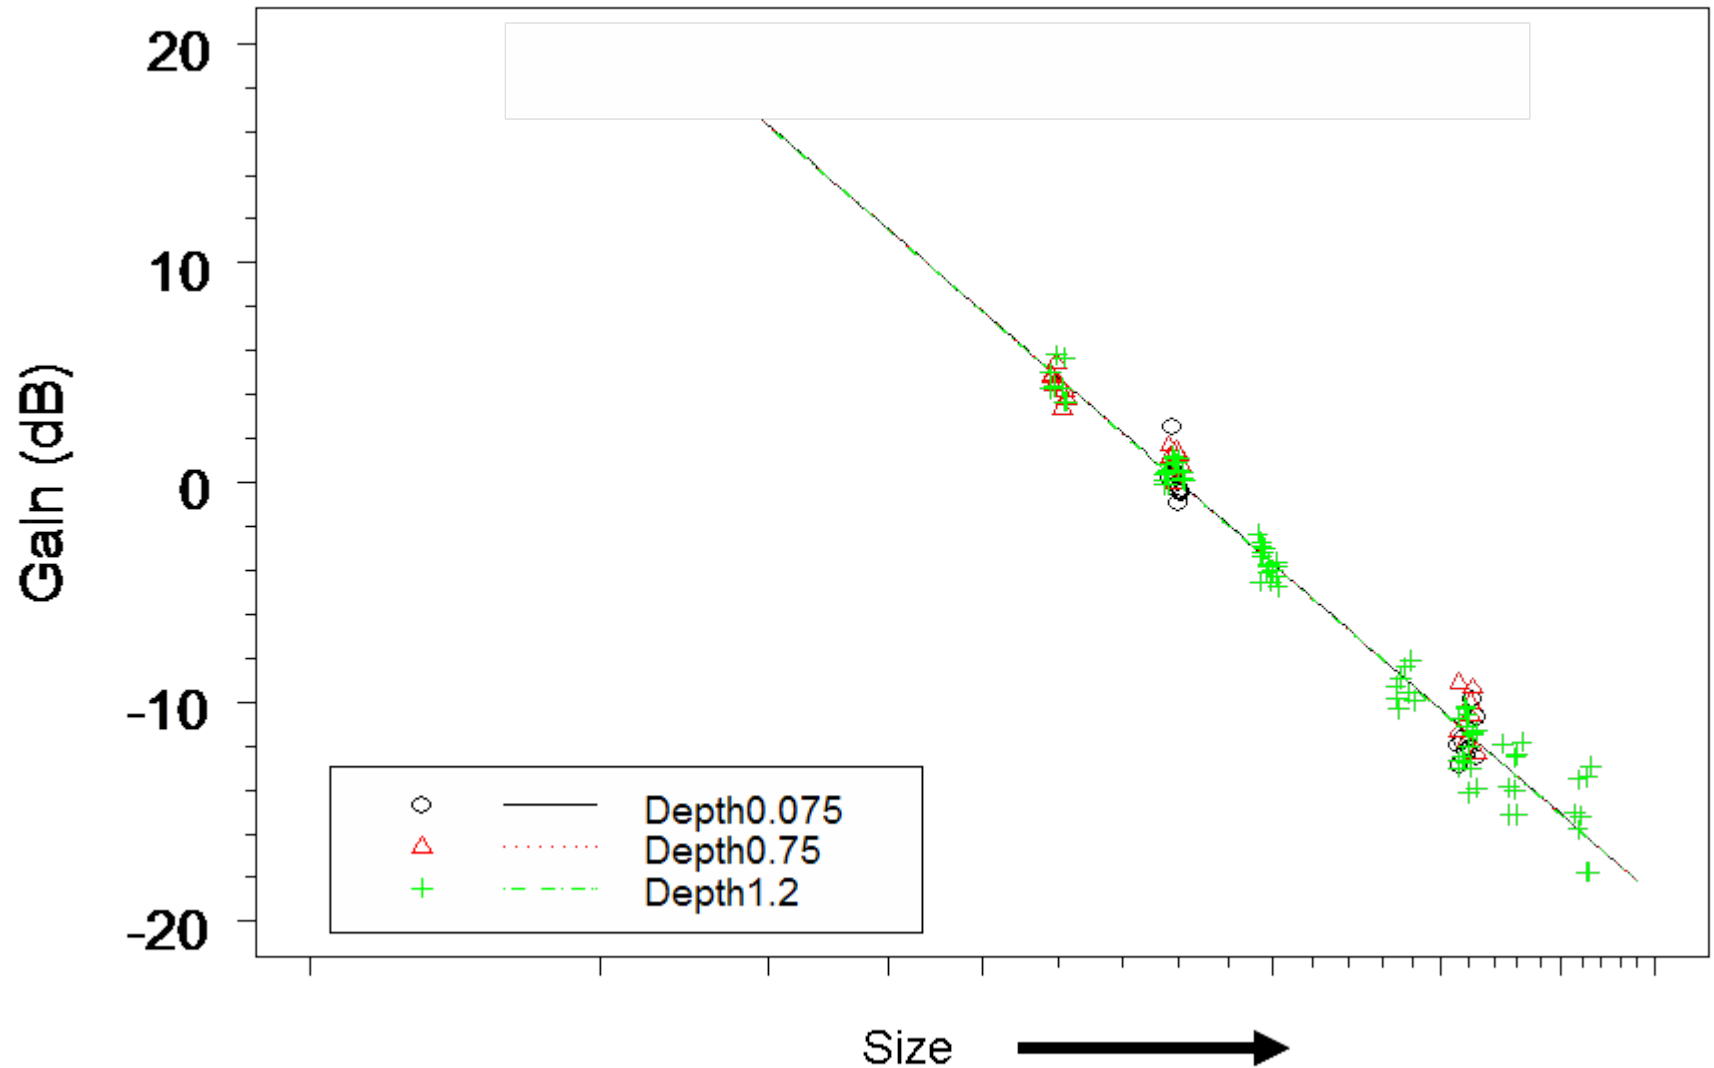

# Step 8. Acquire Marginals for Empirical Factors

- Tests 1 through 8 use indexing of 0.02"
- Two systems:
  - XR pulser is in Tank B
  - HR pulser is in Tank A
- Four transducers:
  - Transducer 1 = KB 002m99
  - Transducer 2 = TLC p90903
  - Transducer 3 = UTX 1 (0004073)
  - Transducer 4 = UTX 6 (0004074)
- Four inspectors

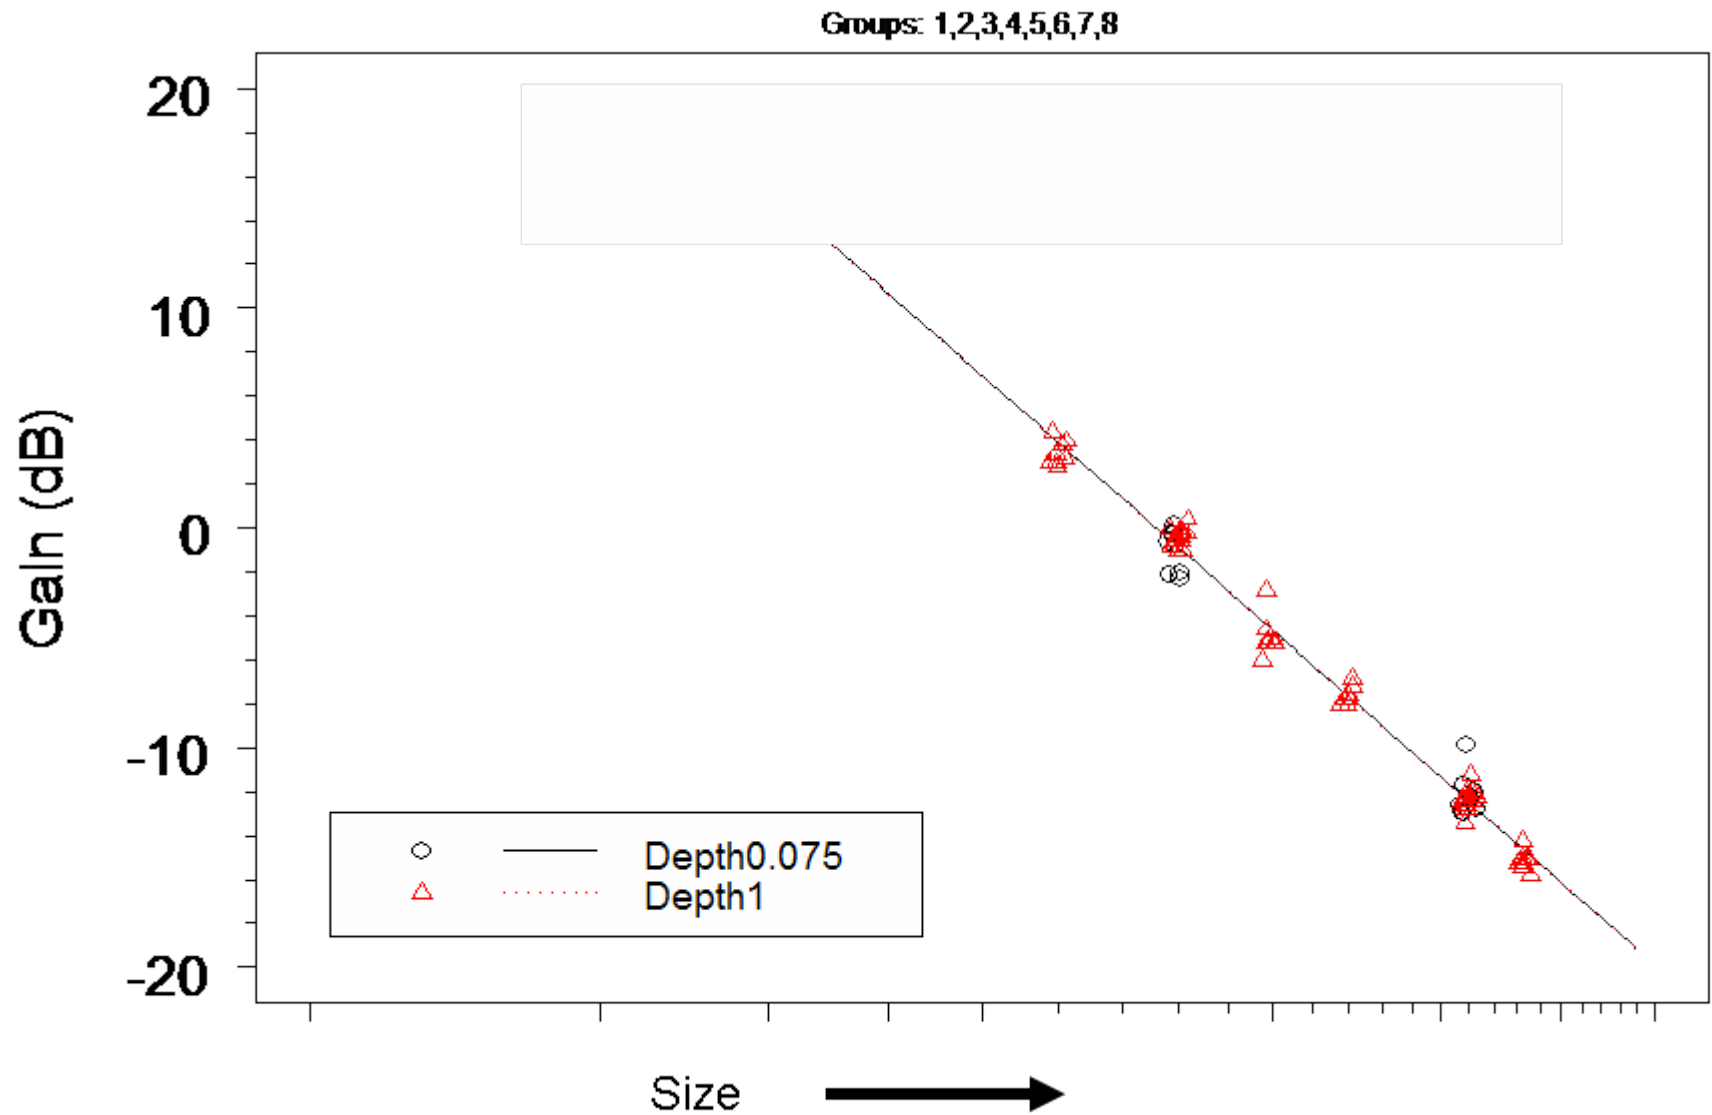

| TEST  | OPERATOR | TRANSDUCER | TANK |
|---|----------|------------|------|
| 1   | A        | 1          | A    |
| 2   | B        | 2          | A    |
| 3   | C        | 3          | B    |
| 4   | D        | 4          | B    |
| 5   | A        | 4          | B    |
| 6   | B        | 3          | B    |
| 7   | C        | 2          | A    |
| 8   | D        | 1          | A    |
| 9 <sup>th</sup> data set is a repeat of one of the test to produce C-scans with 0.005" increments |          |            |      |

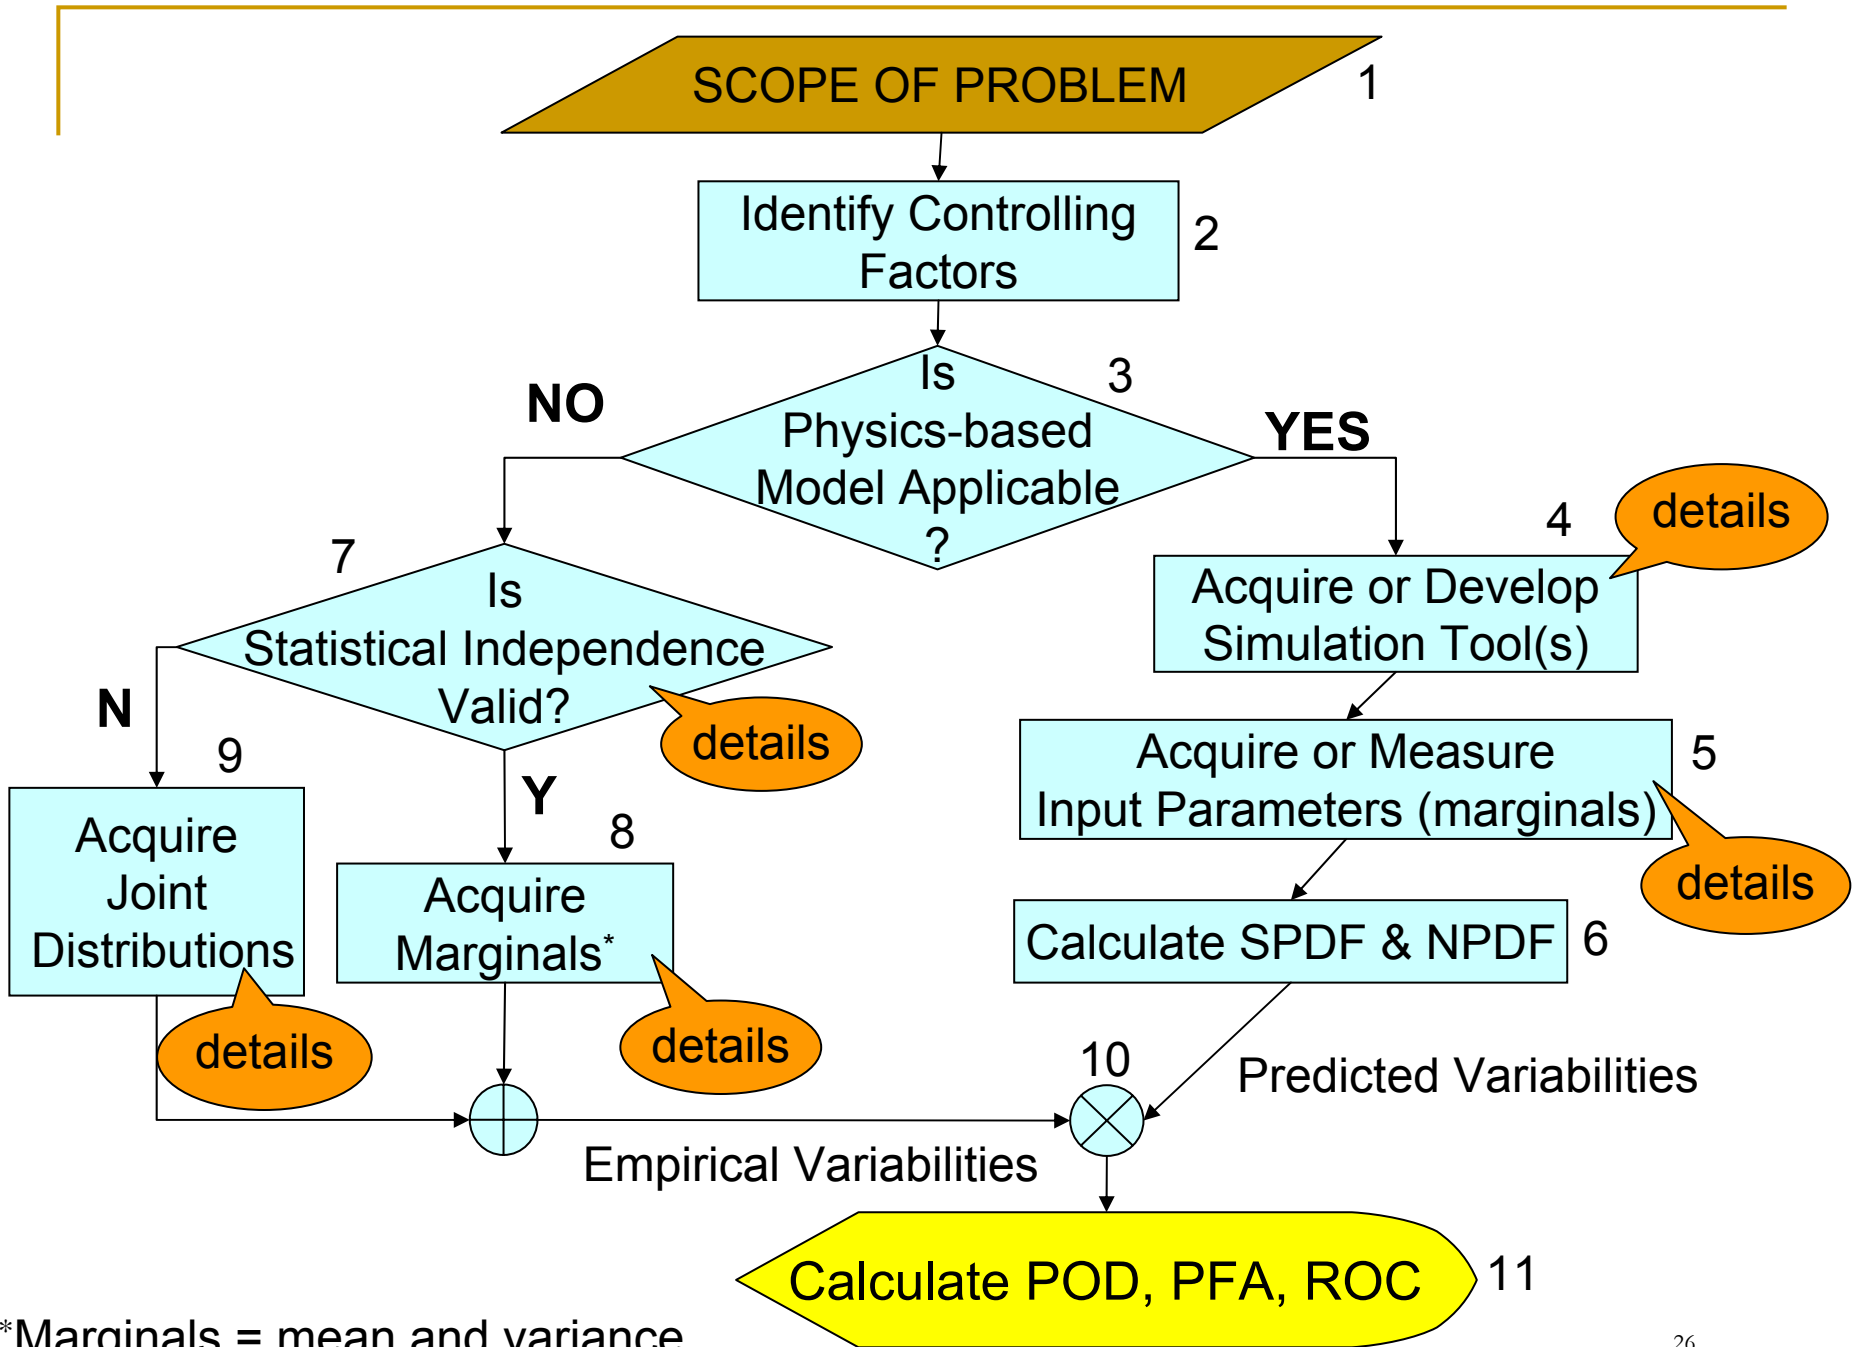

# Surface 1

# Surface 2

\*Marginals = mean and variance

# Step 11. Calculate POD, PFA, ROC

## UT POD – Empirical to Model-Assisted Comparison

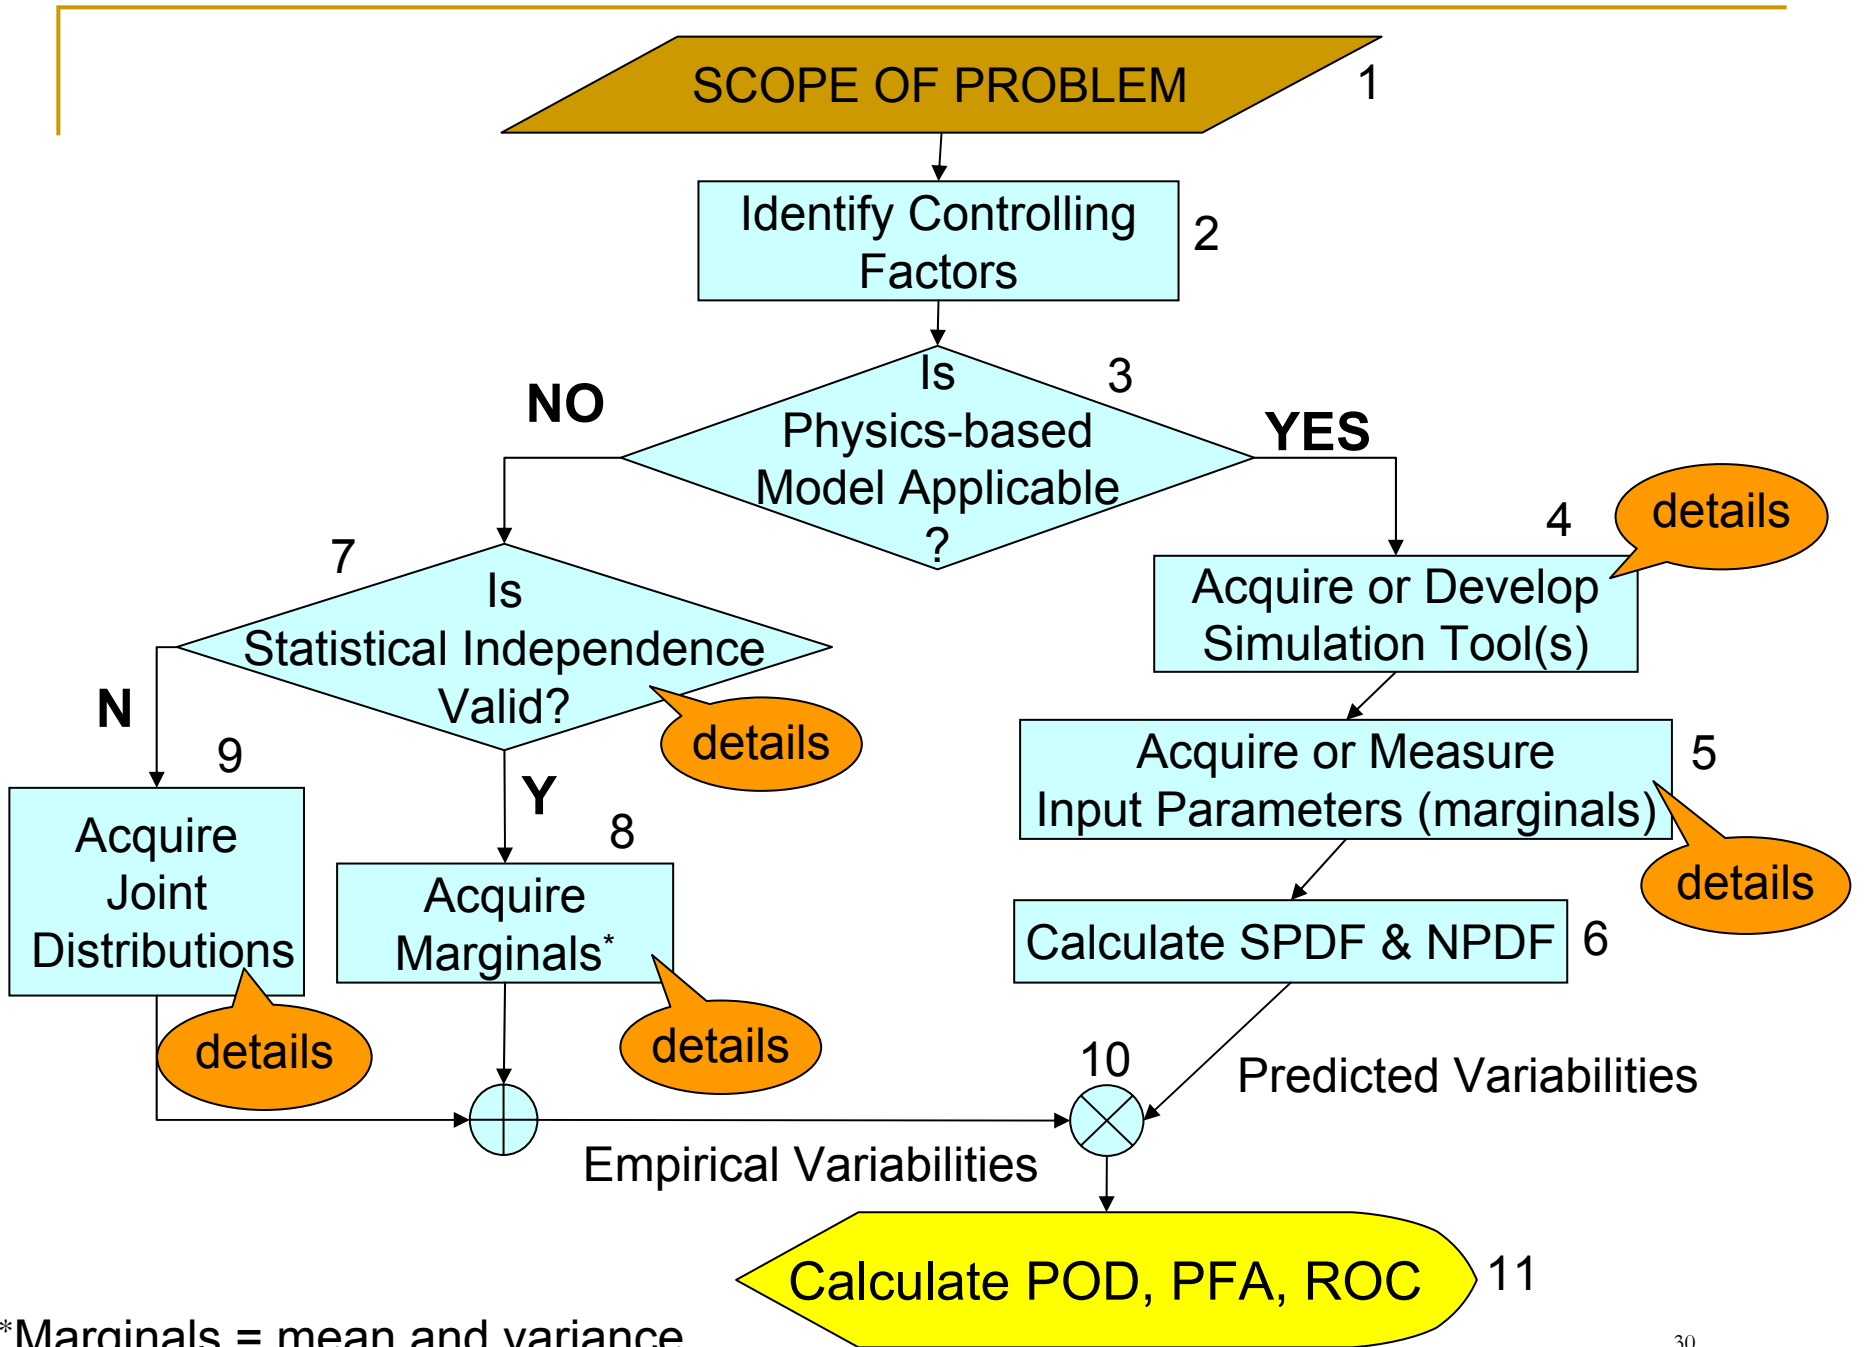

# UT POD - Empirical to Model-Assisted Comparison

- Agreement to within  $\pm 0.0004$ " ( $\pm 0.4$  mils)
- Lead to transducer performance specification to ensure future inspections are in compliance with POD requirements

# Steps to Generate Model-assisted UT POD

- Determine necessary UT properties
- Establish noise distribution for alloy/system using validated model
  - Material noise
  - Electronic noise
- Calculate signal distribution for inspection parameter set using validated model
  - Transducer
  - Threshold, scan plan
- Apply test system variability factor

\*Marginals = mean and variance
